

An optical fiber consists of several channels

Overview

Optical fibers are circular dielectric wave-guides used to contain and transmit light over short or long distances. Such fibers are widely used in fiber-optic communication, where they permit transmission over longer distances and at higher bandwidths (data transfer rates) than. This chapter reviews the main properties of the fiber-optic channel, starting from the structure of ideal linear optical fibers and proceeding to the derivation of the equations governing signal propagation in single-mode fibers in the presence of various physical phenomena. They consist of three elements as shown in Figure 1: a central core, cladding and a protective coating. Additionally, optical fiber is lightweight and less susceptible to noise (no electromagnetic). Fiber Optics is the communications medium that works by sending optical signals down hair-thin strands of extremely pure glass or plastic fiber. The light is "guided" down the center of the fiber called the "core".
