

Data Center APF Application Solution

Overview

Controlled by high-speed IGBT modules with switching frequencies up to 20 kHz and a 1 ms current response time, the APF maintains up to 97% filtering efficiency, ensuring clean and reliable power for data center operations. They provide independent phase regulation, effectively correcting voltage imbalance and ensuring continuous, stable power supply for sensitive IT. Delta's PQC Series APF is connected in parallel with non-linear loads, and uses one set of current transformers (CT) to detect the load current. It calculates each order harmonic current by FFT algorithms in its DSP microchips, and then generates a compensating current with the same amplitude but. Active Harmonic Filters (AHFs) or Active Power Filters (APFs) are advanced solutions engineered to eliminate these distortions by injecting real-time compensating currents—ensuring a clean, sinusoidal waveform. In this blog, we'll explore the most common types of APFs, their applications, and how. In today's rapidly evolving digital economy, data centers serve as the "digital foundation" that handles core functions including computing power output, data storage, and business operations. The 'active' involves actively generating inverse harmonics to cancel out existing harmonics in buses, while the 'passive' means capacitors can be used to absorb harmonics from buses. The fundamental operating principle of APFs is.
