

Internal tripping of relay protection

Overview

A protection relay tripping circuit connects relays to breakers for fast fault isolation. Key components include trip/close coils and anti-pumping relays. Proper design, testing, and maintenance ensure reliable overcurrent, differential, and auto-reclosing protection in power. Over the years, a number of protective relays and schemes have been developed to detect a loss of syn-chronism and to perform the necessary functions to preserve the system. Note that all generators- the power sources – have been disconnected. Tripping relays are used to multiply the number of contacts available, provide isolation between the source and system operating element and meet the required duty. Essential. ng or immediately following out-of-section faults. There are two classifications of sympathetic trips: those which occur due to delayed voltage recovery conditions, and those which.
