

Parallel device voltage busbar

Overview

Busbars are metallic strips, often made of copper or aluminum, that distribute power in high-current DC systems. When configured in parallel topologies, busbars can handle large currents efficiently while minimizing power losses and reducing thermal issues. Temperature variations in the semiconductor can lead to fluctuations in the current flowing through the IGBT (I_c) and affect the threshold voltage ($V_{GE(th)}$). This paper reviews the latest busbar design methodologies and offers design recommendations for both laminated and PCB-based busbars. Because the compensation current generated inside the module is proportional to the bus. As part of my research, I'm doing calculations on a hypothetical high-current (4000 A) medium-voltage (5000 V) DC power transmission system using two parallel busbars. However, I need to decide how the busbars are oriented relative to each other, and I can't find information on what best practices. In 2017, UL 508 harmonized with IEC 60947 for low voltage switchgear and control gear to become UL 60947 - further cementing IEC devices as the industry standard for years to come. Since their introduction into the U., design engineers, integrators, and original equipment manufacturers (OEMs). Following a number of design principles and the circuit topology used in practical applications, a laminated busbar that can improve the current sharing characteristics of the system is designed in this paper, in which the total current exceeds 10kA. For half-bridge module and independent IGBT.
