

Raw materials for hollow optical fiber

Overview

To make an optical fiber, layers of silicon dioxide are first deposited on the inside surface of a hollow substrate rod. This is done using Modified Chemical Vapor Deposition, in which a gaseous stream of pure oxygen combined with various chemical vapors is applied to the rod. An optical fiber is a single, hair-fine filament drawn from molten silica glass. These fibers are replacing metal wire as the transmission medium in high-speed, high-capacity communications systems that convert information into light, which is then transmitted via fiber optic cable. These features make them very promising for. Soda-lime-silicate and sodium-borosilicate glasses were made from materials purified to parts-per-billion (ppb) levels of transition metal impurities by ion exchange, electrolysis, recrystallization, or solvent extraction. In standard silica. What is an Optical Fiber?

Half the thickness of the cladding struts ! Cladding terminates at the edge of a unit cell ! Why Designing HC-ARFs?

10 million times brighter than incandescent lamp! HC-ARF Applications: Telecom.
